Abstract

The increasing frequency of environmental crimes (Rippingille 2023), from illegal deforestation and habitat degradation to biopiracy, requires new digital tools for collecting, verifying, and communicating biodiversity evidence. [GeoPl@ntNet](#) addresses this need by transforming citizen-science and expert plant observations into auditable, high-resolution biodiversity intelligence suitable for research, conservation, and forensic applications.

Built upon the globally used [Pl@ntNet](#) infrastructure, which hosts more than 20 million users contributing georeferenced plant observations from 200 countries, GeoPl@ntNet Leblanc et al. (2025a) integrates this vast dataset with environmental predictors to generate predictive biodiversity maps at 50×50m spatial resolution. At its core, GeoPl@ntNet employs a multi-species deep learning model (DeepSDM Botella et al. 2018) and a Habitat Distribution Model based on a transformer model.

The DeepSDM is first trained on approximately 30 million [Global Biodiversity Information Facility \(GBIF\)](#) species occurrence records and 5 million [European Vegetation Archive \(EVA\)](#) surveys to infer species presence, habitat types, and biodiversity indicators across Europe. The model combines environmental variables, Sentinel-2 RGB and near-infrared

imagery, elevation, land cover, and long-term climatic time series. Species distribution predictions are then computed over a European grid of 50×50 m cells within 25×25 km meta-tiles. The species distribution predictions are subsequently fed into a transformer-based model (PI@ntBERT Leblanc et al. 2025b) to predict habitats under the EUNIS 2020 standard. Finally, derived biodiversity indicators, such as counts of protected, local, or invasive species, are aggregated into reproducible spatial layers that users can explore, download, or integrate via [WMS](#) or [STAC](#) services.

Beyond ecological research, GeoPI@ntNet demonstrates strong potential for environmental forensics. Investigators can detect non-native or invasive taxa near ports and industrial areas, monitor biodiversity decline before and after disturbance events, and generate standardized biodiversity reports that support legal or regulatory proceedings.

GeoPI@ntNet implements a provenance-based auditing system that tracks the full lifecycle of each biodiversity layer. Every map is linked to machine-readable metadata describing the source datasets, model versions, and environmental predictors used to generate it. These metadata are exposed through STAC and WMS services, enabling external verification, reproducibility of outputs, and legally traceable biodiversity reporting.

The platform's design: [Nuxt](#) and [Leaflet](#) for the frontend, Python backend with [MapProxy](#) and [TiTiler](#) services, also ensures transparency and reproducibility, enabling alignment with [TDWG](#) data standards including World Geographic Scheme for Recording Plant species Distributions ([WGSRPD](#)) and [EUNIS habitat classifications](#). By coupling scalable AI models trained on both citizen-science and expert data with diverse maps and reports, GeoPI@ntNet connects biodiversity informatics with environmental governance, enabling auditable, site-level verification of biodiversity integrity.

Accessible via <https://geo.plantnet.org>, the platform will be extended to global coverage and integrated within [PI@ntNet](#) to support scalable and legally robust biodiversity assessments worldwide.

Keywords

biodiversity informatics, species distribution modeling, citizen science, deep learning, habitat mapping

Living Data 2025

Acknowledgements

This work was provided with computer and storage resources by GENCI at IDRIS thanks to the grant 2024-A0171011389 on the supercomputer Jean Zay's V100, A100 and H100 partitions.

Funding program

This work was supported by the European Commission through the GUARDEN (101060693) and MAMBO (101060639) projects.

Conflicts of interest

The authors have declared that no competing interests exist.
